

Daffodil

Narcissus

Blooming dates:
February to early April

Daffodils are bright springtime flowers that grow from bulbs planted in the fall. The plant's stem and leaves will develop underground inside the bulb during the winter and emerge in the spring. A daffodil plant has two or three waxy leaves and usually only has one flower, which has six petals and a trumpet-shaped center. Once the leaves and stem have withered away, the bulb's roots will pull the plant further into the soil so it can regrow next year. Daffodils are beautiful, but they are also toxic! They naturally repel garden pests like deer and rats, and should never be eaten by a pet.
